

BRFSS data

The BRFSS uses a multistage-cluster design based on random-digit dialing to select a representative sample from each state's non-institutionalized civilian residents aged 18 years or older. BRFSS data are directly weighted based on the probability of selection of a telephone number (including cell phones from 2009), the number of telephones in a household, the number of adults in selected households, and geographic or density stratification (Centers for Disease Control [CDC], 2019b). Median cross-state response rates for the BRFSS ranged from 65% (range 38–93) in 1990 (CDC, 1990) to a median of 45% (range 28–60) in 2012 (CDC, 2012a, 2012b). Additional information on the full survey design is available in other publications (CDC, 1990; Dwyer-Lindgren et al., 2013) and online (CDC, 2019a).

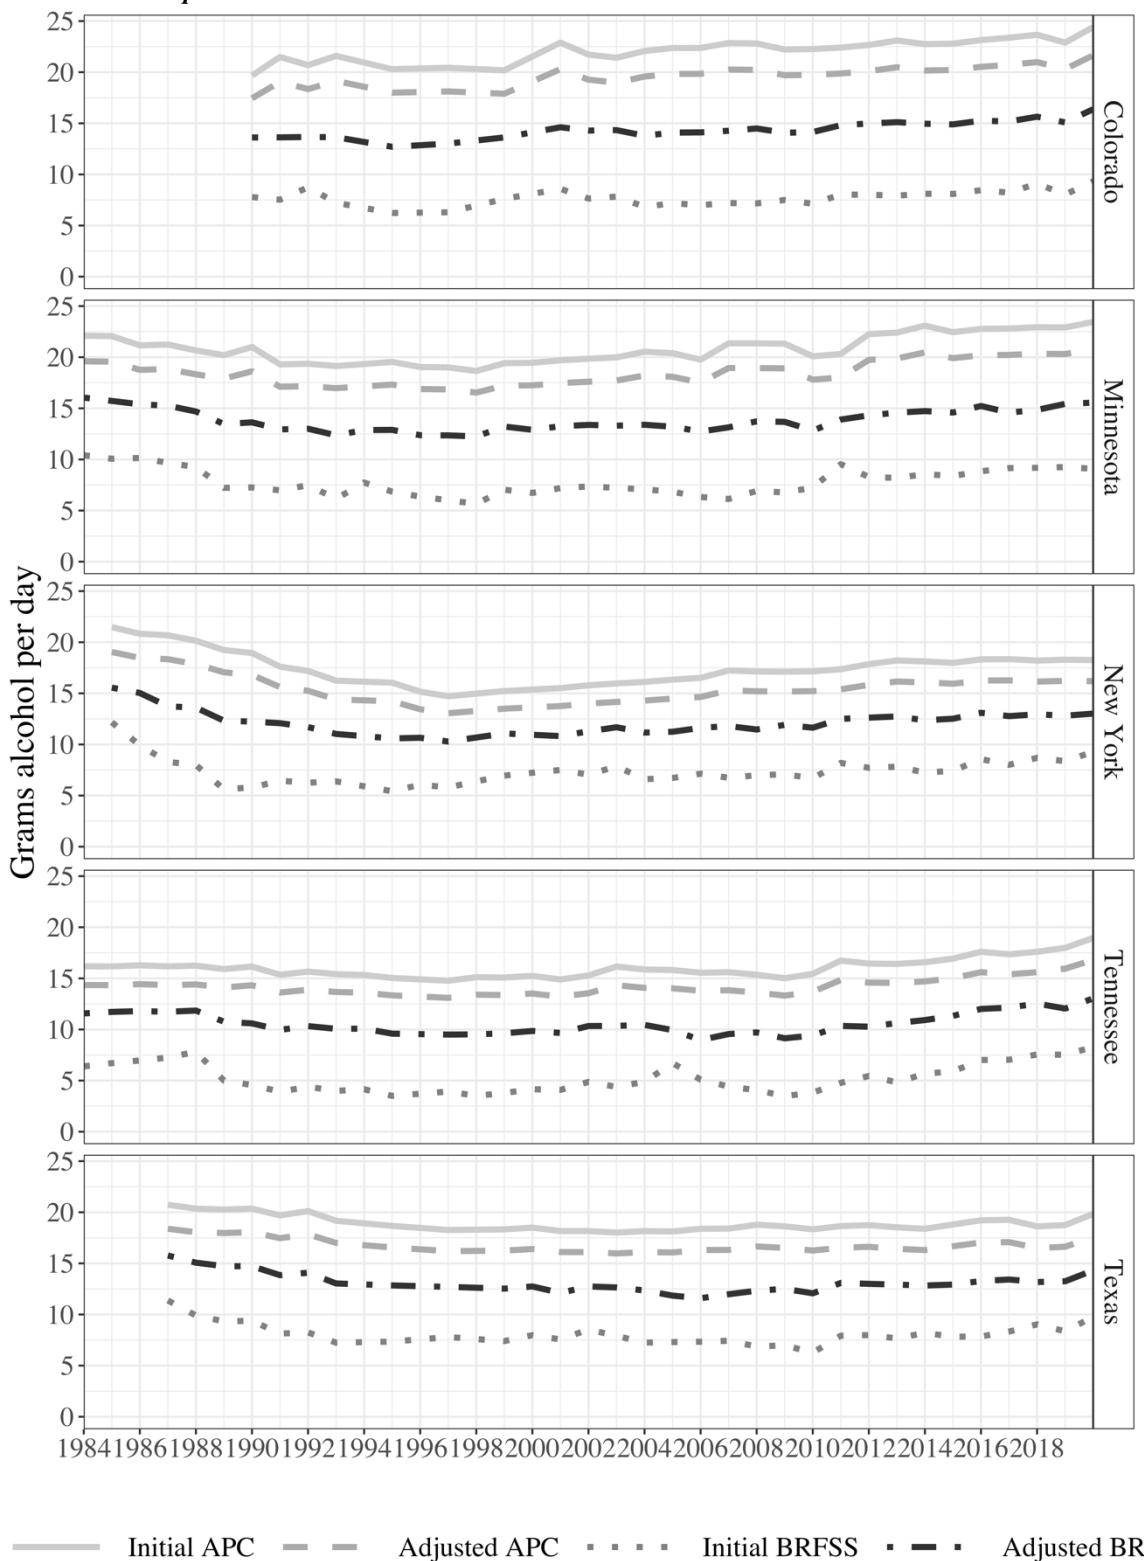

The BRFSS did not consistently collect alcohol use data from every state until after the year 2000 (Yi et al., 2003). In particular, only data from 12 states was collected on alcohol use in 1994, 1996 and 2000, and 17 states in 1996. Therefore, estimates from these survey years may not be nationally representative and should be approached with caution. For an overview of which states collected alcohol consumption data in each year between 1984 and 2001, see Table 2 in Yi et al., 2003. Table A1 summarises the proportion of missing data in each year from 1984 – 2020 for the key demographic indicators used to impute annual drinking prevalence (sex, race and ethnicity and age) as well as alcohol consumption variables. In all years there is a very small proportion (less than 2.5% of observations missing) of missing data for demographic variables. In the years other than 1994, 1996, 1998 and 2000, there is a low proportion of missing data on alcohol use variables (less than 8% of observations missing).

Whilst we have included years with reduced participation from individual states in our national estimates for upshifting, please note that in some of these years up to 80% of the sample are missing alcohol use data. In our approach, we removed all missing data and suggest that data from consecutive years should be pooled if data from individual survey years is missing.

In our approach, we removed all missing data prior to re-allocating the drinking status and up-shifting alcohol use. We suggest that if data from these years with low response are required for individual-level modelling, data from consecutive years should be pooled (i.e. data from 1993 or 1995 used for 1994 estimates).

Figure S1

Comparison of Initial and Adjusted BRFSS Data Compared to Alcohol Per Capita (APC) Sales Data on Alcohol Consumption in Selected US States 1984–2019

— Initial APC - - - Adjusted APC ······ Initial BRFSS - - - - Adjusted BRFSS

Note: Adjusted APC refers to 90% of the APC value that was adjusted to remove alcohol consumed by special populations. Adjusted BRFSS refers to the final adjusted value for the BRFSS after performing the upshifting procedure.
